**L**ithium-ion batteries (LIBs) are the power source of choice not only for popular consumer electronics but also for upcoming electric vehicles.<sup>1–3</sup> So far, various materials, such as graphitic/non-graphitic carbon,<sup>4</sup> transition-metal oxides ( $\text{SnO}_2$ ,<sup>5</sup>  $\text{TiO}_2$ ,<sup>6</sup>  $\text{Fe}_2\text{O}_3$ ,<sup>7</sup>  $\text{Co}_3\text{O}_4$ ,<sup>8–10</sup>  $\text{NiO}$ ,<sup>11</sup>  $\text{MnO}_2$ ,<sup>12</sup>  $\text{MoO}_3$ ,<sup>13</sup>  $\text{WO}_3$ ,<sup>14</sup>), chalcogenides ( $\text{TiS}_2$ ),<sup>15,16</sup> nitrides,<sup>17</sup> polymers,<sup>18</sup> lithium alloys (Si, Sn, Al, Sb)/multinary alloys,<sup>19–21</sup> and their composites,<sup>22–26</sup> have been exploited as the anode materials of LIBs. Among them,  $\text{Co}_3\text{O}_4$  attracts extensive interest for LIBs due to its high theoretical capacity ( $890 \text{ mAh g}^{-1}$ ), more than two times larger than that of graphite ( $372 \text{ mAh g}^{-1}$ ), which are expected to meet the requirements of future energy storage systems.<sup>8–10</sup> However, its large volume expansion/contraction and severe particle aggregation associated with the  $\text{Li}^+$  insertion and extraction process lead to electrode pulverization and loss of interparticle contact and, consequently, result in a large irreversible capacity loss and poor cycling stability.<sup>27,28</sup> A variety of appealing strategies have been utilized to solve these intractable problems, including the use of carbon-based nanocomposites<sup>28–32</sup> and unique  $\text{Co}_3\text{O}_4$  nanostructures/microstructures of nanotubes,<sup>9</sup> nanowires,<sup>27</sup> nanoparticles (NPs),<sup>33</sup> nanorods,<sup>34</sup> octahedral cages,<sup>35</sup> and plates.<sup>10</sup> However, to keep large reversible capacity combined with high Coulombic efficiency, achieving long cycling life and good rate capability of  $\text{Co}_3\text{O}_4$  electrode material still remains a great challenge.

Graphene, a new two-dimensional carbon material, is recently expected to be an

**ABSTRACT** We report a facile strategy to synthesize the nanocomposite of  $\text{Co}_3\text{O}_4$  nanoparticles anchored on conducting graphene as an advanced anode material for high-performance lithium-ion batteries. The  $\text{Co}_3\text{O}_4$  nanoparticles obtained are 10–30 nm in size and homogeneously anchor on graphene sheets as spacers to keep the neighboring sheets separated. This  $\text{Co}_3\text{O}_4$ /graphene nanocomposite displays superior Li-battery performance with large reversible capacity, excellent cyclic performance, and good rate capability, highlighting the importance of the anchoring of nanoparticles on graphene sheets for maximum utilization of electrochemically active  $\text{Co}_3\text{O}_4$  nanoparticles and graphene for energy storage applications in high-performance lithium-ion batteries.

**KEYWORDS:** graphene · cobalt oxide · nanomaterial · anode · lithium-ion batteries · cyclic performance

advanced anode material in LIBs<sup>36–45</sup> due to its superior electrical conductivity, high surface-to-volume ratio, ultrathin thickness, structural flexibility, and chemical stability.<sup>46–50</sup> It has been demonstrated that graphene-based anode materials have large initial discharge capacity ( $600–2042 \text{ mAh g}^{-1}$ ) and reversible capacity ( $540–1264 \text{ mAh g}^{-1}$ ), although they suffer from large irreversible capacity, low initial Coulombic efficiency, and fast capacity fading.<sup>36–40</sup> More importantly, graphene can also be used in composites with metallic or oxide NPs to improve the electrochemical performance of these particles<sup>40–44</sup> because the ultrathin flexible graphene layers not only can provide a support for anchoring well-dispersed NPs and work as a highly conductive matrix for enabling good contact between them<sup>51</sup> but also can effectively prevent the volume expansion/contraction and aggregation of NPs during Li charge/discharge process.<sup>40</sup> Meanwhile, the anchoring of NPs on graphene can effectively reduce the degree of restacking of graphene sheets and consequently

**Figure 1.** Schematic representation of the fabrication process of Co<sub>3</sub>O<sub>4</sub>/graphene composite. (a) Dispersion of chemically derived graphene in isopropyl alcohol–water (1:1, v/v) solution. (b) Formation of Co(OH)<sub>2</sub>/graphene composite in basic solution. (c) Phase transformation from Co(OH)<sub>2</sub>/graphene composite to Co<sub>3</sub>O<sub>4</sub>/graphene composite by calcination.

keep their high active surface area and, to some extent, increase the lithium storage capacity and cyclic performance of graphene-based material.<sup>36,40–43</sup> It is well-accepted that nanomaterials have advantages of good cycling performance and short path length for Li<sup>+</sup> transport over their bulk counterparts due to the large contact area between electrode and electrolyte.<sup>3,52</sup> Therefore, it is believed that the composite of flexible and electrically conductive graphene anchored with nanostructured Co<sub>3</sub>O<sub>4</sub> particles can efficiently utilize the combinative merits of nanosized Co<sub>3</sub>O<sub>4</sub> and graphene and obtain LIBs with superior performance.

Herein, we report a facile strategy to synthesize such composite of Co<sub>3</sub>O<sub>4</sub> NPs anchored on conducting graphene as an advanced anode material for high-performance LIBs. The Co<sub>3</sub>O<sub>4</sub> NPs obtained are 10–30 nm in size and homogeneously anchor on graphene sheets as spacers to keep the neighboring sheets separated. This Co<sub>3</sub>O<sub>4</sub>/graphene nanocomposite displays superior LIB performance with large reversible capacity, high Coulombic efficiency, excellent cyclic per-

formance, and good rate capability, highlighting the importance of the anchoring of NPs on graphene sheets for maximum utilization of electrochemically active Co<sub>3</sub>O<sub>4</sub> NPs and graphene for energy storage applications in high-performance LIBs.

## RESULTS AND DISCUSSION

Figure 1 illustrates the preparation of single-crystalline Co<sub>3</sub>O<sub>4</sub> NPs anchored on graphene by solution-phase dispersion of Co<sup>2+</sup> inorganic salt on graphene in basic (NH<sub>3</sub> · H<sub>2</sub>O) aqueous solution and subsequent transformation of Co(OH)<sub>2</sub>/graphene into Co<sub>3</sub>O<sub>4</sub>/graphene composite by calcination at 450 °C. Figure 2a shows the typical X-ray diffraction (XRD) pattern of the as-prepared Co<sub>3</sub>O<sub>4</sub>/graphene composite. Compared to that of pure Co<sub>3</sub>O<sub>4</sub> (Figure S1 in the Supporting Information), an additional small and low broad (002) diffraction peak appears at 2θ of 24.5–27.5°, which can be indexed into the disorderedly stacked graphene sheets (Figure S2).<sup>53</sup> Moreover, this broad peak is weaker than that of the as-prepared graphene (Figure S2), suggestive of more disordered stacking and

**Figure 2.** Powder XRD pattern (a) and XPS spectra (b) of Co<sub>3</sub>O<sub>4</sub>/graphene composite. Co 2p (c) and O 1s (d) XPS spectra of Co<sub>3</sub>O<sub>4</sub>/graphene composite. The red dot circle in (a) indicates the (002) diffraction peak of graphene sheets in the Co<sub>3</sub>O<sub>4</sub>/graphene composite.

**Figure 3.** (a) SEM image of  $\text{Co}_3\text{O}_4$ /graphene composite. (b) Low-magnification TEM, (c) high-magnification TEM, and (d) HR-TEM images of  $\text{Co}_3\text{O}_4$ /graphene composite. The inset in (c) is the SAED pattern of  $\text{Co}_3\text{O}_4$  NPs with [110] plane in the  $\text{Co}_3\text{O}_4$ /graphene composite, indicative of the well-textured and single-crystalline nature of  $\text{Co}_3\text{O}_4$  NPs.

less agglomeration for graphene sheets in composite. All of the other diffraction peaks can be ascribed to the well-crystallized  $\text{Co}_3\text{O}_4$  with a face-centered cubic (fcc,  $Fd3m$  (227),  $a = 0.808$  nm) structure (JCPDS No. 42-1467).<sup>8</sup> These results indicate that the composite consists of disorderedly stacked graphene sheets and well-crystallized  $\text{Co}_3\text{O}_4$ .

To determine the chemical composition of  $\text{Co}_3\text{O}_4$ /graphene composite, X-ray photoelectron spectroscopy (XPS) measurements were carried out in the region of 0–1300 eV (Figure 2b). The Co 2p XPS spectra of the composite exhibit two peaks at 795.6 and 780.2 eV, corresponding to the Co 2p<sub>1/2</sub> and Co 2p<sub>3/2</sub> spin–orbit peaks of  $\text{Co}_3\text{O}_4$  (Figure 2c).<sup>54</sup> The presence of  $\text{Co}_3\text{O}_4$  can be further confirmed by the O 1s XPS peak at 530.1 eV, which corresponds to the oxygen species in the  $\text{Co}_3\text{O}_4$  phase (Figure 2d).<sup>54</sup> The C 1s (284.6 eV) peak observed is related to graphitic carbon in graphene, and the small O 1s peak at 532.0 eV in the spectrum indicates the presence of residual oxygen-containing groups (such as –OH and –COOH) bonded with C atoms in graphene (Figure 2d).<sup>55</sup> It is important to note that the C/O ratio for graphene in the composite was estimated to be 55.0 after subtracting the oxygen species involved in O–Co chemical bonds of  $\text{Co}_3\text{O}_4$  in the composite, which is much higher than that (10.7) of the as-prepared graphene. It is considered that the decreased oxygen-containing groups are possibly involved in the formation of  $\text{Co}_3\text{O}_4$  anchored on the surface of graphene sheets, and a further study is required to elucidate this point in the future. Such a high C/O ratio of the graphene sheets implies a good electronic

conductivity, which may enable the graphene sheets to serve as the conductive channels between  $\text{Co}_3\text{O}_4$  NPs, and is favorable for stabilizing the electronic and ionic conductivity consequently.

Figure 3 shows scanning electron microscopy (SEM) and transmission electron microscopy (TEM) images of the as-prepared  $\text{Co}_3\text{O}_4$ /graphene composite. It can be seen from Figure 3a and Figure S3 (Supporting Information) that small  $\text{Co}_3\text{O}_4$  NPs are closely anchored on the surface of graphene sheets. Figure 3b,c shows the TEM images of the as-prepared  $\text{Co}_3\text{O}_4$ /graphene composite, from which it can be seen that the  $\text{Co}_3\text{O}_4$  NPs have a size of 10–30 nm and are homogeneously anchored on the thin graphene layers. The selected area electron diffraction (SAED) pattern (inset in Figure 3c) and high-resolution TEM (HRTEM) image (Figure 3d and Figure S4) clearly demonstrate the well-textured and single-crystalline nature of  $\text{Co}_3\text{O}_4$  NPs in the  $\text{Co}_3\text{O}_4$ /graphene composite, consistent with the XRD results. It should be emphasized that, without the presence of graphene, no  $\text{Co}_3\text{O}_4$  NPs were formed at the same conditions as those for the preparation of the  $\text{Co}_3\text{O}_4$ /graphene composite (Figure S5). This result strongly indicates that the presence of graphene plays an essential role in the formation of homogeneous  $\text{Co}_3\text{O}_4$  NPs. Another phenomenon is that, even after a long time of sonication during the preparation of the TEM specimen, the NPs are still strongly anchored on the surface of graphene sheets with a high density, as shown in Figure 3b,c, suggesting the strong interaction between NPs and graphene sheets. We believe that such interaction combined with good mechanical flexibility of graphene sheets pre-

Figure 4. Galvanostatic charge–discharge curves of (a) graphene, (b) Co<sub>3</sub>O<sub>4</sub>, and (c) the Co<sub>3</sub>O<sub>4</sub>/graphene composite cycled at the 1st, 5th, 10th, and 20th between 3 and 0.01 V (vs Li<sup>+</sup>/Li) at a current density of 50 mA g<sup>-1</sup>. (d) Comparison of the cycling performance of graphene, Co<sub>3</sub>O<sub>4</sub>, and the Co<sub>3</sub>O<sub>4</sub>/graphene composite.

vents the agglomeration of NPs to large particles, as shown in Figure S5 (Supporting Information), in the presence of graphene sheets. In addition, the strong anchoring of Co<sub>3</sub>O<sub>4</sub> NPs on graphene sheets enables fast electron transport through the underlying graphene layers to NPs to improve the electrochemical performance.<sup>40</sup> On the other hand, the NPs on the surface of graphene sheets can act as spacers to efficiently prevent the closely restacking of graphene sheets, avoiding/weakening the loss of their high active surface area.<sup>56</sup>

The electrochemical performance of the as-prepared Co<sub>3</sub>O<sub>4</sub>/graphene composite was first evaluated by galvanostatic charge/discharge cycling at a current density of 50 mA g<sup>-1</sup>. For comparison, we also present the result of pure graphene (Figure 4a) and Co<sub>3</sub>O<sub>4</sub> (Figure 4b) prepared by the same procedure under the same electrochemical conditions. Figure 4b,c shows the charge/discharge profiles of the Co<sub>3</sub>O<sub>4</sub> and Co<sub>3</sub>O<sub>4</sub>/graphene composite electrodes in the 1st, 5th, 10th, and 20th cycles. In the first discharge step, both of them present a long voltage plateau at 1.06 V for the Co<sub>3</sub>O<sub>4</sub>/graphene composite and 1.10 V for Co<sub>3</sub>O<sub>4</sub>, followed by a sloping curve down to the cutoff voltage of 0.01 V, indicative of typical characteristics of voltage trends for the Co<sub>3</sub>O<sub>4</sub> electrode.<sup>10</sup> However, no obvious voltage plateau was observed for graphene (Figure 4a).<sup>38</sup> The first discharge and charge capacities are 2179 and 955 mAh g<sup>-1</sup> for graphene, 1105 and 817 mAh g<sup>-1</sup> for Co<sub>3</sub>O<sub>4</sub>, and 1097 and ~753 mAh g<sup>-1</sup> for Co<sub>3</sub>O<sub>4</sub>/graphene composite electrodes. Compared to the theoretical capacity of

bulk Co<sub>3</sub>O<sub>4</sub> (890 mAh g<sup>-1</sup>) and graphite (372 mAh g<sup>-1</sup>), the extra discharge capacity of the Co<sub>3</sub>O<sub>4</sub>/graphene composite may be attributed to the larger electrochemical active surface area of graphene and/or grain boundary area of the nanosized Co<sub>3</sub>O<sub>4</sub> particles.<sup>30,38</sup> The initial capacity loss may result from the incomplete conversion reaction and irreversible lithium loss due to the formation of a solid electrolyte interphase (SEI) layer.<sup>10</sup> Since the second cycle, however, the Co<sub>3</sub>O<sub>4</sub>/graphene composite electrode presents much better electrochemical lithium storage performance than Co<sub>3</sub>O<sub>4</sub> electrode. After five discharge/charge cycles, it exhibits a high reversible capacity of ~800 mAh g<sup>-1</sup>. The Coulombic efficiency rapidly rises from 68.6% in the first cycle to 97.6% in the fifth one and then remains above 98% in the following cycles (Figure 4c). In contrast, the reversible capacity of the Co<sub>3</sub>O<sub>4</sub> electrode rapidly drops to 609 mAh g<sup>-1</sup> with a low Coulombic efficiency of 91.3% after the fifth cycle and then gradually increases to 95.1% for the 20th cycle (Figure 4b). Compared to the Co<sub>3</sub>O<sub>4</sub>/graphene composite and Co<sub>3</sub>O<sub>4</sub> electrodes, the graphene electrode shows larger discharge/charge capacity in the first cycle but suffers from a lower initial Coulombic efficiency (only 43.8%) and fast reversible capacity fading (773 mAh g<sup>-1</sup> for the fifth cycle, 642 mAh g<sup>-1</sup> for the 20th cycle, Figure 4a). More importantly, the Co<sub>3</sub>O<sub>4</sub>/graphene composite exhibits a much better cycling performance than graphene and Co<sub>3</sub>O<sub>4</sub> (Figure 4d). It can be seen that the reversible capacity of graphene and Co<sub>3</sub>O<sub>4</sub> decreases from 955 to 638 mAh g<sup>-1</sup> and from 817 to only 184 mAh g<sup>-1</sup>, re-

Figure 5. Cyclic voltammograms of the  $\text{Co}_3\text{O}_4$ /graphene composite (solid line) and  $\text{Co}_3\text{O}_4$  (dotted line) at a scanning rate of  $1 \text{ mV s}^{-1}$ .

spectively, up to 30 cycles. In contrast, the reversible capacity of the  $\text{Co}_3\text{O}_4$ /graphene composite slightly increases with cycling and reaches  $\sim 935 \text{ mAh g}^{-1}$  after 30 cycles. From Figure 4d and Figure S6 (Supporting Information), it is important to note that there is a strong synergistic effect between  $\text{Co}_3\text{O}_4$  NPs and graphene sheets in the composite, which becomes much more apparent with cycling and plays a central role in the excellent cyclic performance of the  $\text{Co}_3\text{O}_4$ /graphene composite.

Figure 5 presents cyclic voltammograms (CV) of the as-prepared  $\text{Co}_3\text{O}_4$ /graphene composite and  $\text{Co}_3\text{O}_4$  electrodes. In the first cycle, two cathodic peaks were observed at 0.50 and 0.36 V for the  $\text{Co}_3\text{O}_4$ /graphene composite and at 0.51 and 0.26 V for  $\text{Co}_3\text{O}_4$ , corresponding to a multistep electrochemical reduction (lithiation) reaction of  $\text{Co}_3\text{O}_4$  with Li.<sup>8</sup> The observed main anodic peak at 2.24 V for the  $\text{Co}_3\text{O}_4$ /graphene composite and at 2.15 V for  $\text{Co}_3\text{O}_4$  is ascribed to the oxidation (delithiation) reaction of  $\text{Co}_3\text{O}_4$ . The formation of Co and  $\text{Li}_2\text{O}$  and the re-formation of  $\text{Co}_3\text{O}_4$  can be described by the electrochemical conversion reaction:<sup>8,10</sup>

The cathodic peak below 0.8 V for  $\text{Co}_3\text{O}_4$  is broader than that of  $\text{Co}_3\text{O}_4$ /graphene composite partly due to the electrolyte decomposition and formation of the SEI

layer.<sup>10,41</sup> The weak but discriminable reduction and oxidation peaks at 0.045 and 0.21 V/1.0 V, respectively, are observed for the composite electrode but are absent for  $\text{Co}_3\text{O}_4$  due to the insertion/extraction of Li into/from graphene, suggesting that the graphene in the  $\text{Co}_3\text{O}_4$ /graphene composite is also electroactive for lithium storage.<sup>41</sup> In the second cycle, the main reduction peak is shifted to 0.83 V for the  $\text{Co}_3\text{O}_4$ /graphene composite and to 0.66 V for  $\text{Co}_3\text{O}_4$ . The peak intensity and integral areas of the third cycle are close to that of the second one for  $\text{Co}_3\text{O}_4$ /graphene but are obviously decreased for  $\text{Co}_3\text{O}_4$  (Figure 5). These results indicate that the electrochemical reversibility of  $\text{Co}_3\text{O}_4$ /graphene is gradually built after the initial cycle and much better than that for  $\text{Co}_3\text{O}_4$ .

In addition, the  $\text{Co}_3\text{O}_4$ /graphene composite exhibits much better rate capability compared to the  $\text{Co}_3\text{O}_4$  electrode operated at various rates between 50 and  $500 \text{ mA g}^{-1}$  (Figure 6a,b). For example, the  $\text{Co}_3\text{O}_4$ /graphene composite keeps a reversible capacity of  $800 \text{ mAh g}^{-1}$  after the 10th cycle at a current density of  $50 \text{ mA g}^{-1}$ , whereas the reversible capacity of the  $\text{Co}_3\text{O}_4$  electrode rapidly drops from 759 to  $541 \text{ mAh g}^{-1}$ . The following reversible capacity of the  $\text{Co}_3\text{O}_4$ /graphene composite and  $\text{Co}_3\text{O}_4$  electrodes at other various rates is 715 and  $239 \text{ mAh g}^{-1}$  for the 20th cycle at  $150 \text{ mA g}^{-1}$ , 631 and  $122 \text{ mAh g}^{-1}$  for the 30th cycle at  $250 \text{ mA g}^{-1}$ , and 484 and  $53 \text{ mAh g}^{-1}$  for the 40th cycle at  $500 \text{ mA g}^{-1}$ , respectively, with  $\sim 66.2\%$  (only  $\sim 7.1\%$  for  $\text{Co}_3\text{O}_4$ ) of the initial reversible capacity. Moreover, when the rate returns to the initial  $50 \text{ mA g}^{-1}$  after 40 cycles, the composite electrode recovers its original capacity or even a little bit higher ( $767 \text{ mAh g}^{-1}$  for the 50th cycle), but the  $\text{Co}_3\text{O}_4$  electrode cannot go back, as illustrated in Figure 6a,b.

A rough comparison indicates that the reversible capacity ( $935 \text{ mAh g}^{-1}$ ) of the  $\text{Co}_3\text{O}_4$ /graphene composite is much better than those previously reported, such as carbon nanofiber/ $\text{Co}_3\text{O}_4$ <sup>28,29</sup> and mesoporous carbon/ $\text{Co}_3\text{O}_4$ <sup>30</sup> composites, and some unique  $\text{Co}_3\text{O}_4$  nano/microstructures of NPs,<sup>8</sup> nanotubes,<sup>8</sup> nanorods,<sup>8</sup> nanowires,<sup>27</sup> octahedral cages,<sup>35</sup> and plates.<sup>10</sup> The increase of cyclic capacity is different from other appeal-

Figure 6. Rate capability of the  $\text{Co}_3\text{O}_4$ /graphene composite (a) and  $\text{Co}_3\text{O}_4$  (b) at various current densities between 50 and  $500 \text{ mA g}^{-1}$ .

ing strategies for improving electrochemical performance of the  $\text{Co}_3\text{O}_4$  system,<sup>8,27,30,35</sup> demonstrating the excellent cyclic performance of  $\text{Co}_3\text{O}_4$ /graphene composite. The initial Coulombic efficiency (68.6%) of the  $\text{Co}_3\text{O}_4$ /graphene composite is not prominent, but still higher than those of mesoporous carbon/ $\text{Co}_3\text{O}_4$  (55%),<sup>30</sup> NPs (55.2%),<sup>8</sup> nanotubes (58.8%),<sup>8</sup> and nanorods (57.8%).<sup>8</sup> Of importance is that more than  $\sim 98\%$  of Coulombic efficiency was observed after the fifth cycle, indicative of high charge/discharge reversibility of the  $\text{Co}_3\text{O}_4$ /graphene composite electrode.

Combining the highly reversible capacity, excellent cyclic performance, and high Coulombic efficiency with good rate capability, we believe that such composites of graphene anchored with  $\text{Co}_3\text{O}_4$  NPs are a good candidate as anode material of high-performance LIBs. The superior Li-battery performance of the  $\text{Co}_3\text{O}_4$ /graphene composite electrode can be explained as follows: (i) Graphene sheets act as flexible two-dimensional carbon supports for homogeneous anchoring of  $\text{Co}_3\text{O}_4$  NPs. The graphene sheets in the obtained composite not only provide an elastic buffer space to accommodate the volume expansion/contraction of  $\text{Co}_3\text{O}_4$  NPs during Li insertion/extraction process but also efficiently prevent the aggregation of  $\text{Co}_3\text{O}_4$  NPs and the cracking or crumbling of electrode material upon continuous cycling, thus maintaining large capacity, good Coulombic efficiency, high rate capability and cycling stability.<sup>40</sup> (ii) The graphene sheets in the composite have a good electrical conductivity<sup>57</sup> and serve as the conductive channels between  $\text{Co}_3\text{O}_4$  NPs, which decreases the inner resistance of LIBs and is favorable for stabilizing the electronic and ionic conductivity, therefore leading to a higher specific capacity.<sup>52</sup> (iii) Li-ion diffusion strongly depends on the transport length and accessible sites on the surface of active materials.<sup>52</sup> Therefore, it is expected that the  $\text{Co}_3\text{O}_4$  NPs as well as ultrathin graphene sheets in the nanocomposite offer improved energy storage capacity, Coulombic efficiency, and better cycling stability due to the large electrode/electrolyte contact area, short path length for

$\text{Li}^+$  transport, and good stability for nanostructured electrodes.<sup>3,52</sup> (iv) The presence of  $\text{Co}_3\text{O}_4$  NPs between graphene sheets effectively prevents the agglomeration of graphene sheets and consequently keeps their high active surface area, which is favorable for increasing the Li storage capacity of graphene in the composite. On the basis of the above analyses, it is concluded that the synergetic effect between conducting graphene sheets and  $\text{Co}_3\text{O}_4$  NPs is responsible for the excellent electrochemical performance of the overall electrode *via* the maximum utilization of electrochemically active graphene and nanosized  $\text{Co}_3\text{O}_4$ .

## CONCLUSIONS

We developed a facile strategy to synthesize a composite of electrically conductive graphene anchored with  $\text{Co}_3\text{O}_4$  NPs as an advanced anode material for high-performance LIBs. The  $\text{Co}_3\text{O}_4$  NPs obtained are 10–30 nm in size and homogeneously anchored on graphene as spacers to keep the neighboring graphene sheets separated. Moreover, the flexible structure of two-dimensional graphene sheets and the strong interaction between  $\text{Co}_3\text{O}_4$  NPs and graphene sheets in  $\text{Co}_3\text{O}_4$ /graphene composite are beneficial for efficiently preventing volume expansion/contraction and aggregation of  $\text{Co}_3\text{O}_4$  during Li charge/discharge process. Therefore, such a composite is capable of effectively utilizing the good conductivity, high surface area, mechanical flexibility, and good electrochemical performance of graphene as well as the large electrode/electrolyte contact area, short path length for  $\text{Li}^+$  transport, and good stability for nanostructured  $\text{Co}_3\text{O}_4$  particles. As a result, the  $\text{Co}_3\text{O}_4$ /graphene composite exhibits a large reversible capacity ( $\sim 935 \text{ mAh g}^{-1}$  after 30 cycles), excellent cyclic performance, high Coulombic efficiency (above  $\sim 98\%$ ), and good rate capability, highlighting the advantages of anchoring of NPs on graphene sheets for the maximum utilization of electrochemically active  $\text{Co}_3\text{O}_4$  NPs and graphene for energy storage applications in high-performance LIBs.

## EXPERIMENTAL SECTION

**Synthesis of the  $\text{Co}_3\text{O}_4$ /Graphene Composite.** The graphene sheets ( $\leq 3$  layers) used were synthesized by chemical exfoliation of flake graphite powder (500 mesh) and reduction as previously reported<sup>57</sup> and have a C/O ratio of 10.7. The  $\text{Co}_3\text{O}_4$ /graphene composite was prepared as follows. First, 100 mg of graphene was dispersed in 100 mL of isopropyl alcohol–water (1:1, v/v) solution by sonication for 0.5 h and transferred into a three-necked round-bottom flask under argon flow. An appropriate amount of inorganic salts,  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ , followed by ammonia solution ( $\text{NH}_3 \cdot \text{H}_2\text{O}$ , 25 wt %), was slowly added into the above suspension and then stirred for several hours under an argon flow to ensure complete reaction. The obtained  $\text{Co}(\text{OH})_2$ /graphene composite precursor was filtered and dried under vacuum at  $70^\circ\text{C}$ . Finally, the  $\text{Co}(\text{OH})_2$ /graphene composite precursor was calcined at  $450^\circ\text{C}$  in air for 2 h to obtain the  $\text{Co}_3\text{O}_4$ /graphene composite. According to thermogravimetry/differentiate thermogravim-

etry (TG/DTG) analyses (Figure S7 in Supporting Information), the weight percentage of  $\text{Co}_3\text{O}_4$  and graphene in the  $\text{Co}_3\text{O}_4$ /graphene composite was estimated to be  $\sim 75.4$  and  $\sim 24.6$  wt %, respectively. For comparison,  $\text{Co}_3\text{O}_4$  particles were also prepared in the same conditions but without the presence of graphene.

**Materials Characterizations.** The  $\text{Co}_3\text{O}_4$ /graphene composites were characterized by XRD (D/max 2400 with  $\text{Cu K}\alpha$  radiation), XPS (Escalab 250, Al  $\text{K}\alpha$ ), SEM (Nova Nano 430), and HRTEM (JEOL JEM 2010, 200 kV and Tecnai F30, 300 kV), and TG/DTG (Netzsch STA 449C, measured from 30 to  $800^\circ\text{C}$  at a heating rate of  $10^\circ\text{C}/\text{min}$  in air). The  $\text{Co}_3\text{O}_4$  particles prepared without the presence of graphene were characterized by XRD, SEM, and TEM.

**Electrochemical Measurements.** The working electrodes were prepared by mixing 80 wt % active material ( $\text{Co}_3\text{O}_4$ /graphene composite,  $\text{Co}_3\text{O}_4$ ), 12 wt % acetylene black (Super-P), and 8 wt % polyvinylidene fluoride (PVDF, 5 wt %) binder dissolved in

*N*-methyl-2-pyrrolidinone. After coating the above slurries on Cu foils, the electrodes were dried at 120 °C in vacuum for 2 h to remove the solvent before pressing. Then the electrodes were cut into disks (12 mm in diameter) and dried at 100 °C for 24 h in vacuum. For graphene, the electrode was prepared by the same procedure with 70 wt % graphene, 10 wt % acetylene black, and 20 wt % PVDF. Electrochemical measurements were carried out via CR2032 (3 V) coin-type cell with lithium metal as the counter/reference electrode, Celgard 2400 membrane separator, and 1 M LiPF<sub>6</sub> electrolyte solution dissolved in a mixture of ethylene carbonate (EC) and dimethyl carbonate (DMC) (EC/DMC, 1:1 v/v). The cells were assembled in an argon-filled glove-box. CV measurements were carried out using a Solartron 1287 electrochemical workstation at a scanning rate of 1 mV s<sup>-1</sup>. Galvanostatic charge–discharge cycles were tested by LAND CT2001A electrochemical workstation at various current densities of 50–500 mA g<sup>-1</sup> between 3 and 0.01 V vs Li<sup>+</sup>/Li at room temperature.

**Acknowledgment.** This work was supported by Ministry of Science and Technology of China (No. 2006CB932703), National Science Foundation of China (Nos. 50872136 and 50921004), and Chinese Academy of Sciences (No. KJCX2-YW-231).

**Supporting Information Available:** XRD patterns of the Co<sub>3</sub>O<sub>4</sub>, graphene sheets, and Co<sub>3</sub>O<sub>4</sub>/graphene composite, SEM and TEM images of Co<sub>3</sub>O<sub>4</sub>, HRTEM image and TG/DTG analysis of Co<sub>3</sub>O<sub>4</sub>/graphene composite, and the analysis of the maximum utilization of electrochemically active graphene and Co<sub>3</sub>O<sub>4</sub> NPs in composite. This material is available free of charge via the Internet at <http://pubs.acs.org>.
